

Votes against in Prague's City Assembly, 2010–2026

This study asks whether the same councillors vote against less in each new term on the resolutions Prague's assembly adopts; since 2010 it is supported as a pooled average, driven mainly by 2010–14.

PRAHA SOBĚ ON THE SAME SIDE AS SPOLU	88 %

ANO VOTING YES, IN THE COALITION / IN OPPOSITION	95 / 59 %
administrative count · descriptive	

OVERWHELMED? HERE'S THE SHORT VERSION

- The pooled fall rests mostly on the first transition. The same councillors voted against at a fifth of their earlier rate between 2010–14 and 2014–18, at about the same rate between 2014–18 and 2018–22, and at about two thirds of it between 2018–22 and 2022–26.
- The other two registered tests were not supported. The opposition did not withhold its yes more on land use and property than on grants, and a left–right cut sorted the contested votes better than the coalition line, because opposition clubs mostly vote no one club at a time.
- Lists voted yes far more often while they governed than in opposition. The comparison is descriptive, since each new coalition also changed what came to the vote.
- The analysis plan was committed before the results but is self-timestamped, and the four-term fall in votes against had already been published when it was written.

- The files hold only final votes on adopted resolutions, between 55 and 67 % of the roll calls taken, and pressing nothing cannot be told apart from stepping out, so the record says nothing about intent.

Prague's City Assembly publishes its roll calls as open data, one row per vote and one column per councillor¹, and across its four terms since 2010 votes against have become rare on the resolutions it adopts. That leaves three

questions about the change. The first is whether the same councillors changed how they vote or were replaced by others who vote differently. The second is whose no it is when a no is recorded, and whether the chamber divides by government and opposition or by left and right. The third is what the opposition votes against. Legislative scholars have tools for each of these: scaling votes into positions²³, comparing a government–opposition divide with a left–right one⁴, and separating members who change their behaviour from members who are replaced⁵. Hix and Noury compared national legislatures and Theriault decomposed change in the US Congress; this study applies both approaches to a municipal assembly, where coalitions form and fall within a term and a chamber of 65 keeps many of the same people across terms, under a registered analysis plan⁶.

Data

Each cell of the files holds what a councillor did on a vote, and there are five possible entries. *Hlas pro* is a vote for, *hlas proti* against, *zdržel se* an abstention. *Nehlasoval* means the councillor was in the room and pressed nothing, and *chyběl* means absent. A resolution needs 33 votes for, a majority of all 65 seats, so the three ways of not voting for have the same legal effect, since none of them counts towards the 33, and they differ only in what goes on the record.

The current term, from its first session in November 2022 to September 2026, holds 2 468 votes over 42 sessions, read here member by member, and the whole record since 2010 holds 10 565 roll calls. The files hold votes on substantive items only, not on the agenda or procedure, and in practice one final vote per resolution⁷. Rejected proposals and amendments are almost absent: in the current term, two votes in the file failed. Comparing the numbered votes of each sitting with the rows published shows that the files hold between 55 and 67 % of the roll calls taken. The missing ones are procedural votes, agenda changes and amendments, and in national parliaments those are the votes on which government and opposition fight most^{8,9}. Everything in this article is therefore about the final votes on the resolutions the assembly adopted, which records how it reached the resolutions it passed and leaves out much of what it argued about. Because the files are the whole published record, not a sample of it, the shares and rates computed from them directly are administrative counts with no sampling error; intervals are given for the registered estimates.

Clubs are the lists councillors were elected from, taken from the Statistical Office's candidate registers¹⁰. For the current term they were checked against the clubs on the city's own list of councillors¹¹, and the only difference is Hana Kordová Marvanová, discussed below. The councillor-to-list crosswalk for all four terms is published with the design⁶. The dates on which each list entered and left the coalition come from coalition agreements and news reports¹², and resolution titles for 2022–2026 from the city's resolution register¹.

How this was done

The design of the four-term study is a registered analysis plan. It was committed to the repository at 3830f59 on 28 September 2026 at 22:39, before the commit that holds the results (a79f48f) at 22:53, and the branch carrying both was pushed after the analysis, so the order of the two rests on self-reported commit times⁴. It fixes the hypotheses, one test for each and the decision rules, and the three confirmatory tests share a family-wise error rate of 5 % through Holm's procedure¹³.

When the plan was written, the first version of this article, published earlier on 28 September, had already reported that on passed votes the rate of voting against fell in every term, from 1.06 per 100 councillors present in

2010–14 to 0.28, along with the current term's agreement between clubs and the abrupt fall in abstentions after 2018. The direction of H1 was therefore partly known in aggregate. What had not been computed was any comparison within councillors across terms, any scaling, anything by subject or by coalition status; §0 of the design lists everything that had been seen.

H1's estimand is the average change in a councillor's log rate of voting against between consecutive terms, adjusted for the change in how much of the term their club spent in opposition. It mixes change over time with career stage, which person-level data cannot separate. Inference is over people, 59 of them in 73 pairs of terms, by a sign-flip test. Everything that changed after registration is listed, dated, at the end of the design file and below.

The tests

Hypothesis	Test	Result
H1 · the same councillors vote against less, term after term	within-person change < 0, pooled over three transitions	supported × 0.49 per term, p < 0.001; mainly 2010–14
H3 · votes split along coalition and opposition better than along left and right	classification errors	not supported left-right cut fits better
H4 · the opposition opposes planning and property more than grants	difference in non-support	not supported -0.4 pp, one-sided p = 0.53

The table keeps the registered numbering. H2, on when abstentions fell, was registered as description because the fall had already been published (§0 of the design), so it has no test and the table skips from H1 to H3. It is reported under "Abstentions before and after 2018".

The coalition and the opposition clubs, 2022–2026

Since 15 February 2023 Prague has been governed by SPOLU (ODS, TOP 09, KDU–ČSL), the Pirates and STAN, 36 of the 65 seats¹⁴. For each vote and each club, the club's position here is yes if more than half of its members present voted for, and anything else if not. Measured that way, STAN took the same side as SPOLU, the mayor's club, on 98 % of the votes, and the Pirates on 97 %.

■ coalition ■ Praha sobě, in opposition ■ rest of the opposition, non-affiliated

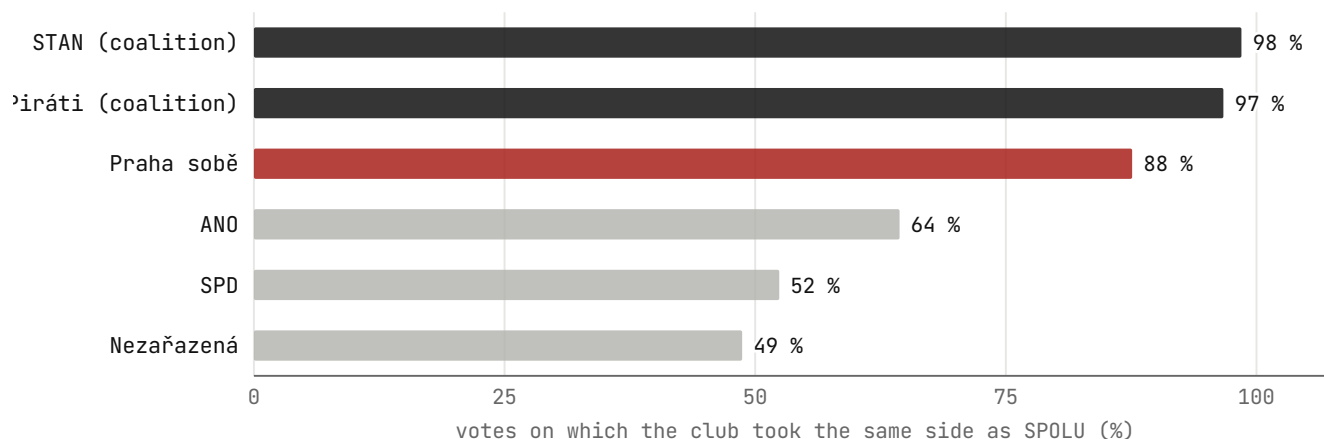

fig. 1 · Same side as SPOLU, share of 2 468 votes, November 2022 – September 2026; administrative count. A club's side is yes when more than half of its members present voted for. Black: coalition; red: Praha sobě, in opposition; grey: the rest of the opposition and the one non-affiliated member. Data: ZHMP roll calls, accessed 28 September 2026.

Praha sobě, with 11 seats, has been outside the coalition for the whole term, yet it took the same side as SPOLU on 88 % of the votes. ANO, the largest opposition club, did so on 64 %, and SPD on 52 %. The one councillor outside every club is Kordová Marvanová, elected for SPOLU and expelled from its club in February 2023 after she did not vote for Bohuslav Svoboda as mayor¹⁵. She is counted on her own here, so her votes never move SPOLU's position. Taken quarter by quarter, Praha sobě stays close to the coalition apart from two dips, in the third quarter of 2024 and the first of 2026. In both of those sessions a third of its members present pressed nothing and several were absent, and in neither did the club vote against.

Votes against, abstentions and pressing nothing, 2010–2026

Of the 143 360 entries recorded this term while councillors were present, 403 are "against". There are 1 269 abstentions and 25 734 cases of pressing nothing. Every club, in government or in opposition, records disagreement almost entirely by not voting: for ANO, 98 % of its members' present non-yes votes are *nehlasoval*, for SPOLU 98 %, and for the Pirates 84 %.

The same files for the three earlier terms show that on the resolutions that passed, the rate of "against" has fallen in every term since 2010, from 1.06 per 100 councillors present to 0.28. In 2010–2014, 11.5 % of passed votes drew at least one vote against, and in this term 4.5 % did. Over the same years, pressing nothing rose from 12 to 18 per 100 present.

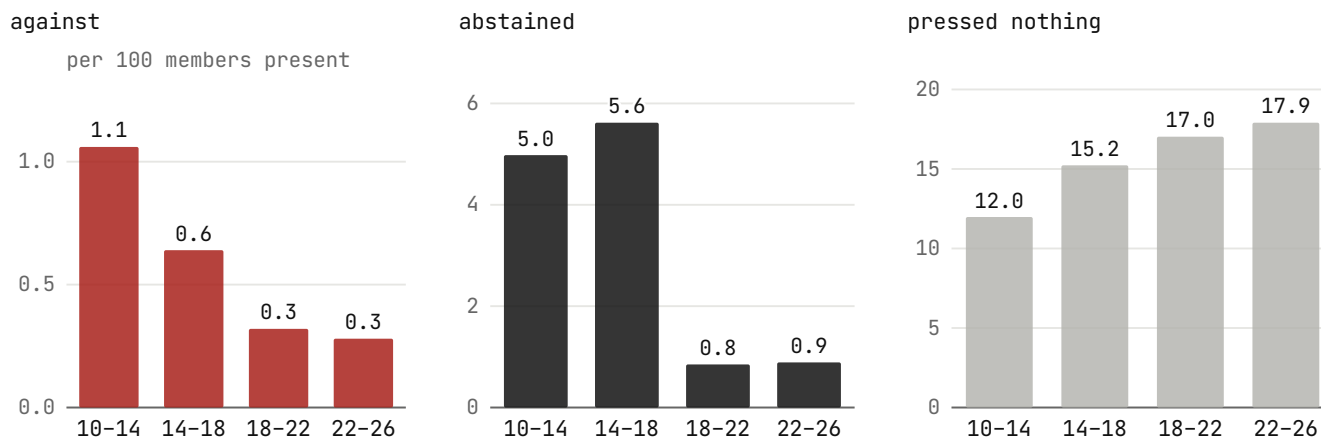

fig. 2 · How present councillors who did not vote for recorded it, per 100 present, on passed votes only, four terms; administrative count. Each panel has its own scale. The fall in abstentions after 2018 is discussed under "Abstentions before and after 2018". Data: ZHMP roll calls, accessed 28 September 2026.

The numbers fit a reading in which Prague's politics has become more consensual, because most items are negotiated before they reach the floor and what is left to vote on is already agreed, and equally one in which disagreement has moved off the record. Pressing nothing is the one way of not supporting a resolution that nobody has to explain, whereas a vote against is a position. The roll calls cannot choose between the two readings, although under either of them a reader of the record now learns less about who opposed what than a reader in 2010 did.

The same councillors across consecutive terms

Fifty-nine people sat in two consecutive terms and were seated for at least 300 votes in each, 73 such pairs in all. For each pair the test compares a councillor's rate of voting against with their own rate one term earlier. It uses only votes against, because they need a button press, so no change in how the system records a member who presses nothing can move them. The same people also move between government and opposition, and opposition councillors vote against more, so each change is adjusted for the change in how much of the councillor's term their club spent in opposition. With that adjustment, the pooled estimate puts a councillor's rate of voting against in the next term at 0.49 times their own earlier rate ($p < 0.001$, sign-flip test over 59 people). This average combines three transitions that went differently, and most of it comes from the first (fig. 3).

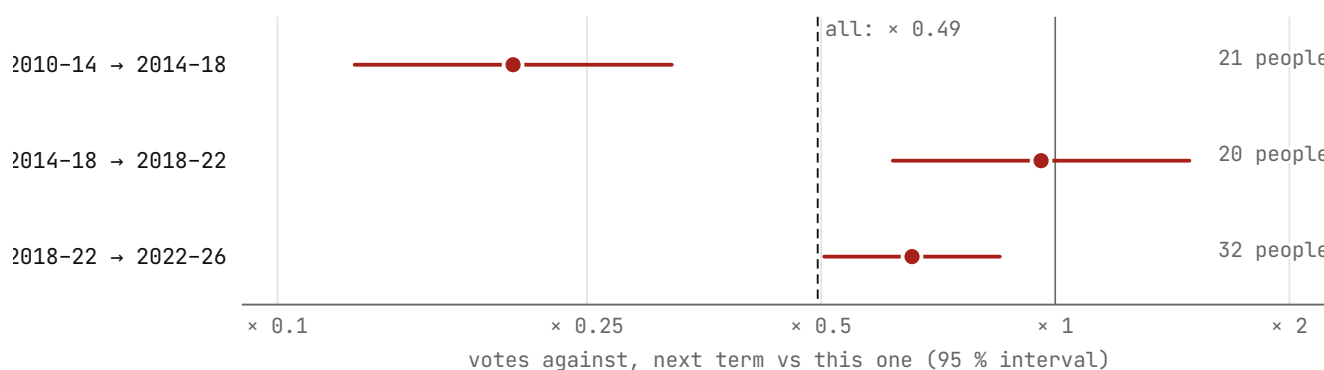

fig. 3 · A councillor's rate of voting against in the next term relative to their own rate this term, adjusted for moving between coalition and opposition, by transition (21, 20 and 32 people). 95 % intervals over people; dashed line: pooled estimate. Data: ZHMP roll calls and crosswalk, accessed 28 September 2026.

Between 2010–14 and 2014–18 the same 21 people voted against at 0.20 times their earlier rate (95 % CI 0.13–0.32), and about half of the assembly's fall in that transition came from the councillors who stayed, the rest from who left and who arrived. Between 2014–18 and 2018–22 the 20 people who stayed voted at 0.96 times their earlier rate (95 % CI 0.62–1.49), and nearly all of the fall in the assembly's rate, 0.35 votes against per 100 present, came from who left and who arrived. Between 2018–22 and 2022–26 the 32 people who stayed voted at 0.65 times their earlier rate (95 % CI 0.50–0.85). Without the first transition the pooled ratio is 0.72, and among the 26 people whose coalition status never changed it is 0.86 ($p = 0.14$), so the registered result holds as a pooled average and does not describe a steady halving in each term. Each new cohort has also arrived voting against less than the one before it: 0.67 per 100 present among 2014's newcomers, 0.30 among 2018's and 0.26 among 2022's.

Yes votes in the coalition and in opposition

Setting each list's share of yes votes side by side for the periods it governed and the periods it did not, using the coalition dates from agreements and news reports¹², shows how large the adjustment for coalition status is.

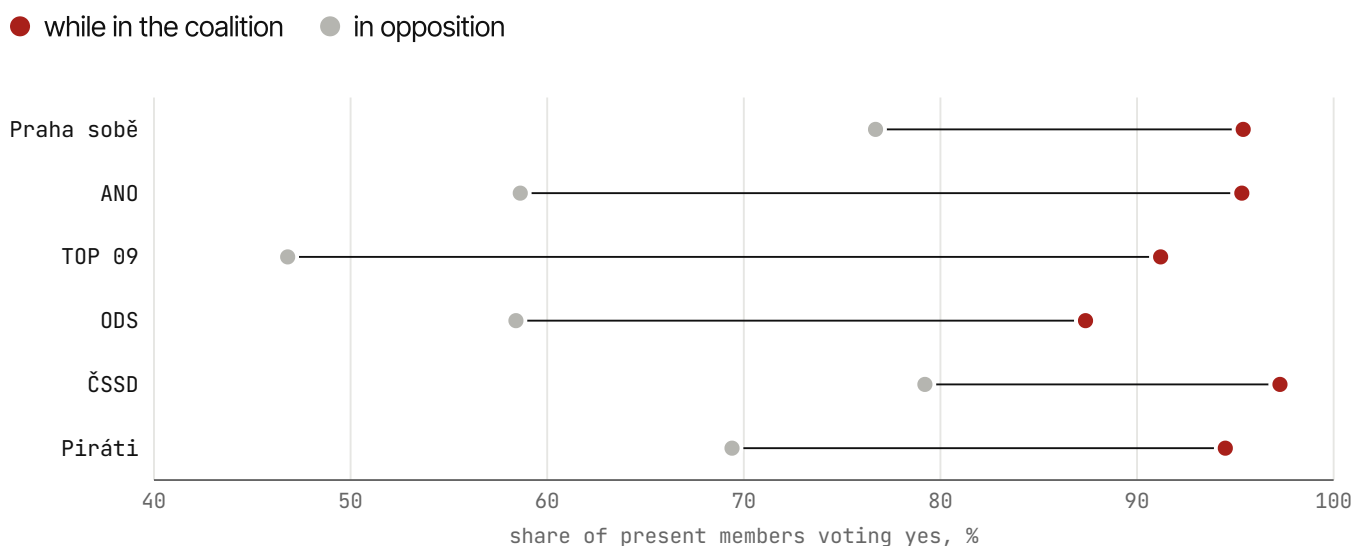

fig. 4 · Share of present members voting yes, by list, averaged over the periods it governed (red) and the periods it did not (grey), 2010–2026, weighted by votes; administrative count. Interregna, when no coalition governed, are left out. ODS in 2022–26 ran inside SPOLU and is not in its row. Data: ZHMP roll calls, accessed 28 September 2026; coalition dates¹².

TOP 09 voted yes 91 % of the time while it led the city in 2011–14, and 43 % in opposition in 2016–18. ANO voted yes 95 % in the coalition of 2014–18, and 58–60 % in opposition since. Praha sobě, a local movement, voted yes 95 % in the coalition of 2018–22 and 77 % in opposition since 2023, which is still the most of any opposition club and matches how close it sat to SPOLU in fig. 1. Each list that has both governed and opposed thus voted differently in the two roles. New coalitions also bring new agendas, so the comparison is descriptive and does not separate the effect of governing from the effect of what each coalition put to the vote.

Coalition and opposition, or left and right

H3, following Hix and Noury⁴, tested whether on the contested votes a single dividing line between coalition and opposition sorts the councillors better than a cut along the left–right order of their national parties. For left and right the design used the Chapel Hill expert survey¹⁶: economic left–right for 2018–22, and general left–right for 2022–26, where the economic scale lines the coalition up next to itself (Appendix B of the design).

The best left–right cut made 10 fewer errors per 100 councillors than the coalition–opposition line in 2018–22 (95 % CI 8–12, bootstrap by sitting) and 6 fewer in 2022–26 (95 % CI 3–8), and the reason lies in which clubs vote no (fig. 5).

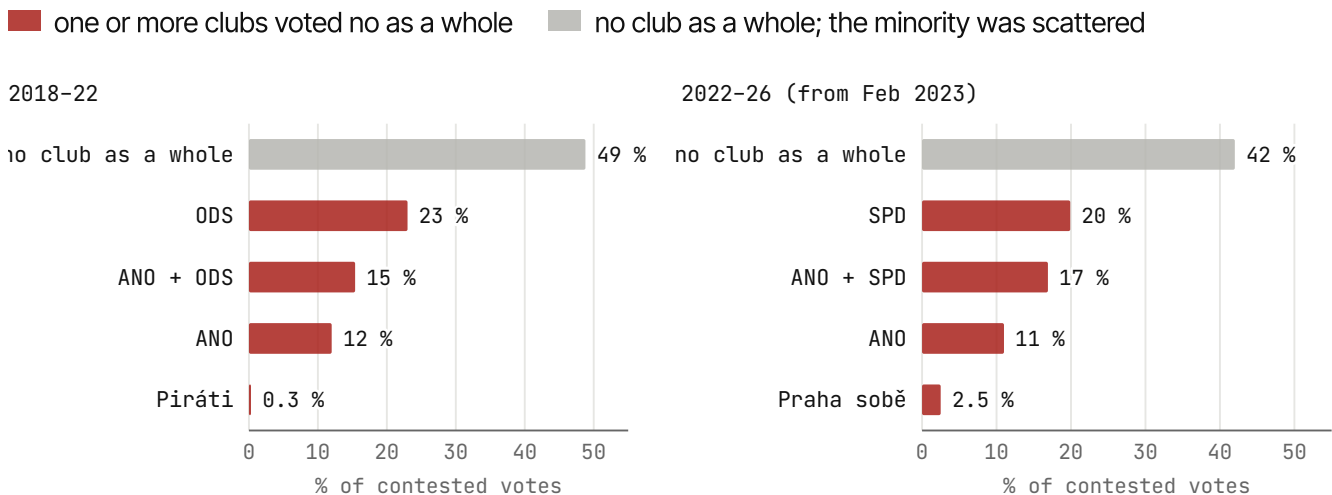

fig. 5 · Contested votes (at least 2.5 % of present members on the losing side) by which clubs had a majority not voting yes, 2018–22 and 2022–26; share of contested votes, administrative count. Red: one or more clubs voted no as a whole; grey: no club did, and the minority was scattered. Data: ZHMP roll calls, accessed 28 September 2026.

In fig. 5 the coalition clubs almost never vote no, and when a club does, it is usually one opposition club on its own. In 2018–22, ODS did so alone on 23 % of the contested votes, ANO alone on 12 %, and the two together on 15 %. In 2022–26, SPD did so alone on 20 %, ANO alone on 11 %, and the two together on 17 %. A left–right cut can separate ODS, or SPD, from everyone else, because they sit at one end of the scale. A single line between coalition and opposition cannot, because it must put ANO on the same side as them. The registered comparison gave left–right that flexibility, since any cut was allowed against two fixed sides, and that asymmetry was in the design before the data were seen. It is reported, and the test is not re-specified.

A one-dimensional scaling of the votes, reported as description³, still puts every coalition club on one side and every opposition club on the other in both terms. In 2018–22 the Pirates score +0.96, Praha sobě +0.82 and the TOP 09 and STAN list +0.20, against ANO at –1.06 and ODS at –1.10. In 2022–26 the Pirates score +0.83, STAN +0.70 and SPOLU +0.58, against Praha sobě at –0.39, SPD at –1.08 and ANO at –1.23. The main line in the assembly therefore runs between government and opposition, while the noes on the opposition side come from separate clubs voting on their own.

Every councillor, 2022–2026

The table reads the current term's file one councillor at a time; click a heading to sort, and the buttons filter by club. The three lowest attendance records, between 60 and 67 %, all belong to members of Praha sobě, and they account for most of the dips in its quarterly agreement with SPOLU, when its members were absent and did not vote against. The councillors who most often record a vote against are all in opposition, three of the top five in SPD, which matches SPD's place in fig. 5. The highest count of votes against by any councillor this term is below thirty.

Present is the share of votes, while they held the seat, at which the voting system recorded them as present (anything but *chyběl*); it cannot tell whether they were in the room. Yes and pressed nothing are shares of the votes at which they were present; abstained and against are counts of votes. "With own club" is how often their vote (yes or not yes) matched their club's side, "with SPOLU" how often it matched the mayor's club. Absence has many reasons (illness, parental leave, another office) and the file records none of them. The one councillor without a club, Hana Kordová Marvanová, has no "with own club". Replacements show the dates they held the seat; one STAN replacement has no name in the file. Data: [members2022.json](#).

What the opposition votes against

Resolution titles were sorted into subjects by a keyword dictionary. It was fixed before any title was joined to a vote, and checked against an independent coding of 200 titles it had not been tuned on (agreement 90.5 %, κ 0.88)⁴. The expectation was that land-use changes and property deals, where Prague's scandals have been, would draw more opposition than grants, but on the 2 237 council-proposed votes since February 2023 they do not. Opposition councillors present withheld a yes on 41 % of grant votes, 41 % of property votes and 37 % of land-use votes, and the registered contrast is -0.4 pp (90 % CI -7.8 to 7.1 pp, standard errors clustered by sitting; one-sided $p = 0.53$). The lowest shares are on the budget (30 %) and on appointments (31 %), so the opposition's no is spread across the agenda instead of gathering on development.

Abstentions before and after 2018

Abstentions fell abruptly between 2014–18 and 2018–22 (fig. 2), and nothing documented changed in how votes are taken. The rules of procedure were amended in 2019, a change the assembly's own transcript calls mostly technical. The chair asked "for, against, abstaining?" in the same words from 2015 to 2023, and new voting equipment came only in 2023. The open data changed how it counts "present" in October 2020, but that field is not used here.

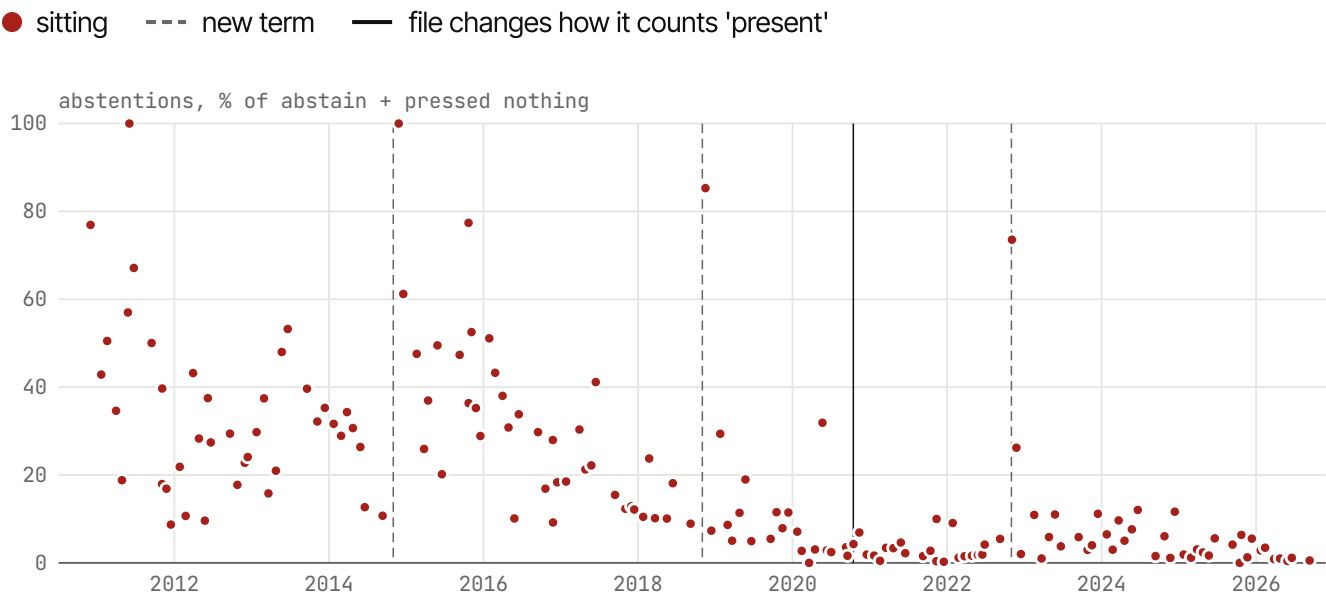

fig. 6 · Abstentions as a share of the two ways of being present without voting yes (abstaining, pressing nothing), per sitting, 2010–2026; administrative count. Dashed: new terms. Solid: the month the open data changed its count of "present". Data: ZHMP roll calls, accessed 28 September 2026.

Read sitting by sitting (fig. 6), abstaining fades within each term, and at the 2018 boundary it steps down further than that trend alone would produce. The step appears even among the 20 councillors who sat in both terms, which argues against pure turnover and for something the councillors shared, such as a norm, a club practice or a habit of how the room votes. This analysis was registered as description, so no test is claimed for it.

Robustness and data checks

H1 variant	People	Ratio per term	p
registered: adjusted for coalition status, all votes	59	× 0.49	< 0.001
without the adjustment for status	59	× 0.59	0.006
passed votes only	59	× 0.47	< 0.001
without the 2010–14 → 2014–18 transition	42	× 0.72	0.004
only people whose status never changed	26	× 0.86	0.14

Among the 26 whose status did not change, the point estimate still shows councillors voting against less, but a group of that size is too small to show it with confidence. In the current term, the city's list gives each councillor's current club only, so a move between clubs earlier in the term that news reports missed would not show here. A seat left vacant goes to the next substitute on the same list¹⁷, which is how the file's one unnamed column, voting from April 2025 after a STAN councillor left, is assigned to STAN. In 10 % of the rows, nearly all from 2026, the count of votes for printed in the file is one or two higher than the named columns add up to, because replacements have no column of their own, so the club shares for 2026 rest on fewer members.

What changed after registration

- 28 September 2026, before estimation: for 2022–26 the left–right axis moved from economic to general left–right, a pre-specified fallback applied because on the economic scale the coalition occupies a contiguous stretch.

- 28 September 2026, after estimation: three pieces were added after the results and are labelled as such in the text, namely the breakdown by which club says no, the one-dimensional scaling, and the comparison of lists in and out of government.
- 28 September 2026, after estimation: the decomposition of the assembly's change is two-way (councillors who stayed; entry, exit and mix), not the registered three-way split with a club term.
- 28 September 2026, not run: a conditional logit and bounds for who returns (H1), alternative contested-vote cut-offs (H3), and an audit against complete session records.

The full list, the councillor-to-list crosswalk and every source are in the repository⁶.

What this means

The files measure final votes on adopted resolutions, between 55 and 67 % of the roll calls taken; procedural votes and amendments are mostly missing. On those votes the rate of voting against fell in every term, from 1.06 per 100 councillors present in 2010–14 to 0.28, an administrative count. The registered estimate puts the same councillors' rate in the next term at 0.49 times their earlier rate ($p < 0.001$, 59 people), a pooled average driven mainly by the first transition: 0.20 (95 % CI 0.13–0.32) between 2010–14 and 2014–18, 0.96 (95 % CI 0.62–1.49) between 2014–18 and 2018–22, and 0.65 (95 % CI 0.50–0.85) between 2018–22 and 2022–26, not a steady halving in each term. On the 2 237 council-proposed votes since February 2023 the opposition was not shown to withhold its yes more on land use and property than on grants (–0.4 pp, 90 % CI –7.8 to 7.1 pp). Whether disagreement has become rarer or has moved off the record is an inference the roll calls cannot settle. None of the estimates is a causal effect, so they do not show what a change of rules, coalition or procedure would do.

What this does not show

Pressing nothing cannot be told apart from stepping out while logged in, from the chair not voting, from a declared conflict of interest, or from a club's collective decision, so the record shows what was pressed and says nothing about intent. Absence has reasons the files do not record either. Party positions are national expert scores for national parties, Prague's lists are not always those parties, and Praha sobě has no score at all. A third to a half of the roll calls are not in the files. The tests do not name or rank individual councillors, and the table of councillors reports the published record for each of them without judging it. None of the estimates, including the comparison of lists in and out of government, is a causal effect. Why abstentions stepped down in 2018 is still unexplained.

Reproduction

Every number on this page comes from the scripts below, run from the repository root in this order. Each runs under `uv run` with the packages named in its header (pandas; NumPy and SciPy for the estimates; matplotlib for the figures) on Python 3; package versions are not pinned in the repository. Raw downloads are written to `tools/data/zhmp/`, which is not committed, and their SHA-256 hashes are listed in [prague-council-files.sha256](#). The two Chapel Hill files are downloaded by hand from chesdata.eu into `tools/data/zhmp/ches/`.

1. [tools/zhmp/votes.py](#): the 2022–26 roll-call file and candidate list; writes `votes2022.json` and `members2022.json`.
2. [terms.py](#): the three earlier terms; writes `terms.json`.
3. [titles.py](#): resolution titles for 2022–26 from the resolution register, one request per second.
4. [topics.py](#): the subject dictionary, with counts from titles alone.
5. [council.py](#): the shared loader and the design-stage structure report.
6. [clubs.py](#): the councillor-to-list crosswalk.
7. [council_extended.py](#): every registered estimate and robustness variant; writes `council_extended.json`.
8. [figures.py](#) and [figures_extended.py](#): the static figures.
9. [tools/charts/prague_council.py](#): the data behind the interactive figures.

Change log

- 28 September 2026: first published as "Prague's council rarely says no" (the current term), and extended the same evening with the registered four-term study.
- 29 September 2026: correction. The header gave ANO's yes share in opposition as 58 %; weighted by votes, as fig. 4 is, it is 58.6 %, which rounds to 59 %.
- 29 September 2026, version 2: retitled "Votes against in Prague's City Assembly, 2010–2026", and the deck limited to the resolutions the assembly adopts. "Pre-registered" replaced by the registered-analysis-plan wording with commit hashes. Disclosed that the four-term fall in votes against was published before H1 was registered. H1 restated as a pooled average driven mainly by 2010–14, with n and 95 % CI for each transition in the text. The causal sentence in the comparison of lists in and out of government

removed. The gap in hypothesis numbering explained; the earlier note that a research assistant had seen the H2 answer replaced by the reason the design gives (§0). Added from council_extended.json: 95 % CIs for the H3 error differences (8-12 and 3-8), and the people and p-values in the robustness table (0.006; 42 people, 0.004). Facts strip cut to four cards (the "1 of 3 tests passed" card and Praha sobě's 95 / 77 % dropped from the header; the latter stays in the text). The quarterly opposition chart (former fig. 2) cut to keep six figures, and the remaining figures renumbered. The speculation in the former fig. 3 caption, the "contact at City Hall" line and the duplicated table definitions cut. Access dates added to refs 1, 7, 10, 11 and 16; sections reordered and references renumbered by first citation. The H4 contrast given in pp with its 90 % CI (-7.8 to 7.1 pp, from the clustered standard error of 4.41 pp in council_extended.json, t with 35 df as registered), matching the one-sided test. Two decomposition sentences corrected against the shift-share in council_extended.json: in 2010-14 → 2014-18 about half of the assembly's fall came from councillors who stayed (the text had said all of it), and in 2014-18 → 2018-22 nearly all of it, not the whole, came from turnover. Reproduction section added. Series renumbered: the parking study is Part 5.

- 29 September 2026: added the section What this means.
 - Checked against editorial standard v1 on 29 September 2026.
